This document library is locked down such that the only users who can edit are certain known users. I have now been given the task of updating the file from another user. The only way I can currently think to do this is to copy the file locally and then change the ACL and upload it back. This seems like a very round about way to do it. Is there a better way of accomplishing this task? A: When the document library is locked down to these known users, these users should have permission to edit the document library in SharePoint designer. In other words, these users should have edit permission to the document library. If the users with edit permission are not the same as the one that locked down the document library, what I would do is the following: Copy the file to a different location using the "Move" option under the File menu in SharePoint Designer. Change the ACL to the new user so that the new user can edit the file. Upload the file back to the original location. If you don't want to copy the file to a different location and upload it back, then you will have to do something like what you mentioned in your question. 11]], although the vast majority were CIN3 \[@CR36]]. Our study compared HPV infection and detection rates for genital and anal canal specimens. The prevalence of HPV in the anal canal was lower than in the genital area. HPV was detected in approximately 40% of anal samples but in only about 5% of cervical samples. This suggests that anal specimens may provide more information on HPV prevalence and type-specific distribution of HPV than the cervical specimens, but sample size remains a limitation. Nevertheless, anal HPV prevalence is high in HIV-positive MSM, and anal lesions are highly prevalent in HIV-positive MSM \[@CR37], \[@CR38]]. The fact that the assay for anal HPV had a good sensitivity, even though its specificity was not acceptable, might be related to the high prevalence of HPV-positive anal samples. The State of the Art Wireless telephone systems, both cellular and wireless in nature, have been in widespread use for over two decades. Recently the wireless telephone industry has experienced explosive growth as more people take advantage of the convenience of wireless telephones over the established land line telephone systems. Because of the explosive growth in this industry, the concept of a wireless telephone service as a replacement for the existing land line telephone service is now a reality for millions of people. Wireless telephone networks are primarily designed for use in a single building or small group of buildings. In most wireless telephone systems, a number of base stations are interconnected by one or more switching systems to provide telephone services for a group of users. A base station may provide its services to a number of users within its transmission range. The users, in turn, can communicate with other telephone users by establishing a voice or data link with the base station. The base station and switching system are, however, designed for the service area. As new users and their base stations become established, the network may be able to handle the added users. However, if the base stations are connected to a single switching system, the connections to and from the various users within a particular area may overload the switching system. The number of users, or load, of a particular switching system is normally measured in units of trunks. The load of a switching system is the maximum number of trunks that it can handle at the same time. If a particular switching system is already operating at its capacity, it may be unable to handle an additional load. In such a case, the additional number of trunks is carried over a secondary switching system. In the alternative, the additional load may be accommodated by extending the capacity of the switching system. A primary switching system, however, may be unable to handle an increased load. The primary switching system is designed to handle the maximum number of trunks it can accommodate at the same time. In the
